

Manual

It is recommended to run the software using the provided Linux shell scripts. The *setup.sh* script should always be ran first using the following command:

```
./setup.sh
```

In order to train a new model, you can optionally configure the hyperparameters near the top of the *classifier.py* file. Once you are ready, run the following command in the main project directory:

```
./train.sh
```

The training script will ask for the name of a project found in the *datasets* folder, it will search for a *.csv* file starting with that name. The training script can also be ran with extra command line arguments to specify the name of the project and how many runs to execute beforehand:

```
./train.sh pytorch
```

```
./train.sh pytorch 20
```

By default you should expect training to finish within two minutes, and the best model that was trained in the set number of runs across all scores will be output to the *work* directory. The trained model can be evaluated with an unseen document using a command such as the one below:

```
./evaluate.sh work/pytorch-model.pt test.txt
```

The trained model can also be evaluated with standard input from the terminal when provided with fewer command line arguments:

```
./evaluate.sh work/pytorch-model.pt
```

```
./evaluate.sh
```
